

CampusLoop Backend Technical Document

1. Introduction

CampusLoop is a university-based marketplace platform designed to enable students to buy, sell, and rent items inside the university ecosystem. The backend of CampusLoop is built using **Node.js**, **Express**, **TypeScript**, and **MongoDB**, following a **Modular MVC Architecture Pattern**.

This report explains the backend implementation approach, development standards, authentication logic, wallet flow, error handling strategy, and major design decisions. As this is a lab report, the explanation focuses on concepts, code patterns, architecture decisions, and implementation details without attaching full source code.

2. Backend Architecture Overview

The backend follows a **Modular MVC** structure where each module is completely isolated and contains its own:

- Routes
- Controllers
- Services
- Models
- TypeScript interfaces
- Validation logic

Directory Structure Example

```
src/  
  modules/  
    auth/  
      auth.route.ts  
      auth.controller.ts  
      auth.service.ts  
      auth.model.ts  
      auth.interface.ts  
    item/
```

```
    item.route.ts
    item.controller.ts
    item.service.ts
    item.model.ts
    item.interface.ts
  utils/
  config/
  middlewares/
  app.ts
  server.ts
```

This structure ensures maintainability, testability, and clean separation between layers.

3. Key Design Decisions

3.1 TypeScript Enforcement

TypeScript is used across all modules for:

- Enforcing strict typing
- Improving code reliability
- Detecting errors at compile time
- Ensuring consistent data contracts between layers

All important entity definitions (Role, Status, ItemCategory, JWT payloads, Wallet structure) are stored in `.interface.ts` files.

4. Authentication & Authorization System

The platform uses role-based authentication with four defined roles:

Role	Description
BUYER	Can buy/rent items
SELLER	Can sell/rent items
ADMIN	Internal moderation

SUPER_ADMIN	Full system control
-------------	---------------------

4.1 JWT Authentication Flow

1. The route calls `checkAuth(...allowedRoles)` middleware.
2. The token is extracted from either:
 - `req.headers.authorization`
 - or `req.cookies.accessToken`
3. Token is verified using JWT.
4. User status must be ACTIVE.
5. Decoded payload (email, role, id) is attached to `req.user`.
6. Controller receives a fully authenticated context.

Token Generation Example

```

3  export const generateToken = (payload: JwtPayload, secret:string, expiresIn:string)=>{
4      const token = jwt.sign(payload, secret, {
5          expiresIn
6      } as SignOptions)
7      return token
8  }
9
10 export const verifyToken = (token: string, secret: string) =>{
11     const verifiedToken = jwt.verify(token, secret)
12     return verifiedToken
13 }

```

4.2 University Email Validation

All users must register using a valid **@cse.bubt.edu.bd** email.

The system extracts a student ID from the email prefix using `extractUniversityId()` before creating the account.

```

4 export const extractUniversityId = (email:string):string=>{
5   if(!email.endsWith("@cse.bubt.edu.bd")){
6     throw new AppError(HttpStatus.BAD_REQUEST, "Please Register with BUBT Edu mail");
7   }
8   const universityId = email.split("@")[0];
9
10  // check if it's all digits (since student IDs are numeric)
11  if (!/^\d+$/.test(universityId)) {
12    throw new Error("Invalid student ID format in email.");
13  }
14  return universityId
15 }

```

5. Request Handling & Error Management

CampusLoop strictly follows a **centralized error handling mechanism**.

5.1 Controller Pattern (using catchAsync)

Every controller is wrapped with `catchAsync`:

```

1 import { NextFunction, Request, Response } from "express";
2
3 /* eslint-disable @typescript-eslint/no-explicit-any */
4 type AsyncHandler = (req: Request, res: Response, next: NextFunction) => Promise<void>
5
6 export const catchAsync = (fn: AsyncHandler) => (req: Request, res: Response, next: NextFunction) => {
7   Promise.resolve(fn(req, res, next)).catch((err: any) => {
8     next(err)
9   })
10 }

```

5.2 Error Throwing Convention

Errors are thrown using `AppError`:

```
throw new AppError(HttpStatus.BAD_REQUEST, "Invalid student email");
```

The global error handler receives all thrown errors and formats them consistently.

```

1  class AppError extends Error {
2      public statusCode: number;
3
4      constructor(statusCode: number, message: string, stack = '') {
5          super(message) // throw new Error("Something went wrong")
6          this.statusCode = statusCode
7
8          if (stack) {
9              this.stack = stack
10         } else {
11             Error.captureStackTrace(this, this.constructor)
12         }
13     }
14 }
15
16 export default AppError

```

6. Standard Response Structure

All successful responses follow a single convention through `sendResponse()`:

```

16 export const sendResponse = <T>(res: Response, data: TResponse<T>) => {
17     res.status(data.statusCode).json({
18         statusCode: data.statusCode,
19         success: data.success,
20         message: data.message,
21         meta: data.meta,
22         data: data.data
23     })
24 }

```

This ensures:

- uniform API responses
- easier frontend integration
- improved debugging and testing consistency

7. Database Layer (MongoDB + Mongoose)

Mongoose Models

Each module has its own model file following typed schema definitions.

```
10 > const itemSchema = new Schema<IItem>( ...
71   },
72   {
73     timestamps: true,
74     versionKey: false,
75   }
76 );
77
78 export const Item = model<IItem>("Item", itemSchema);
79 |
```

8. Route Registration

All feature modules are combined in a single routing hub:

```
8   export const router = Router()
9
10  const moduleRoutes = [
11    {
12      path: '/user',
13      route: UserRoutes,
14    }, {
15      path: '/auth',
16      route: AuthRoutes,
17    }, {
18      path: '/item',
19      route: ItemRoutes,
20    }, {
21      path: '/rent',
22      route: RentRoutes,
23    }, {
24      path: '/admin',
25      route: AdminRoutes,
26    }
27  ]
28
29
30  moduleRoutes.forEach((route) => {
31    router.use(route.path, route.route);
32  });
```

In `app.ts`, everything is prefixed with `/api/v1`.

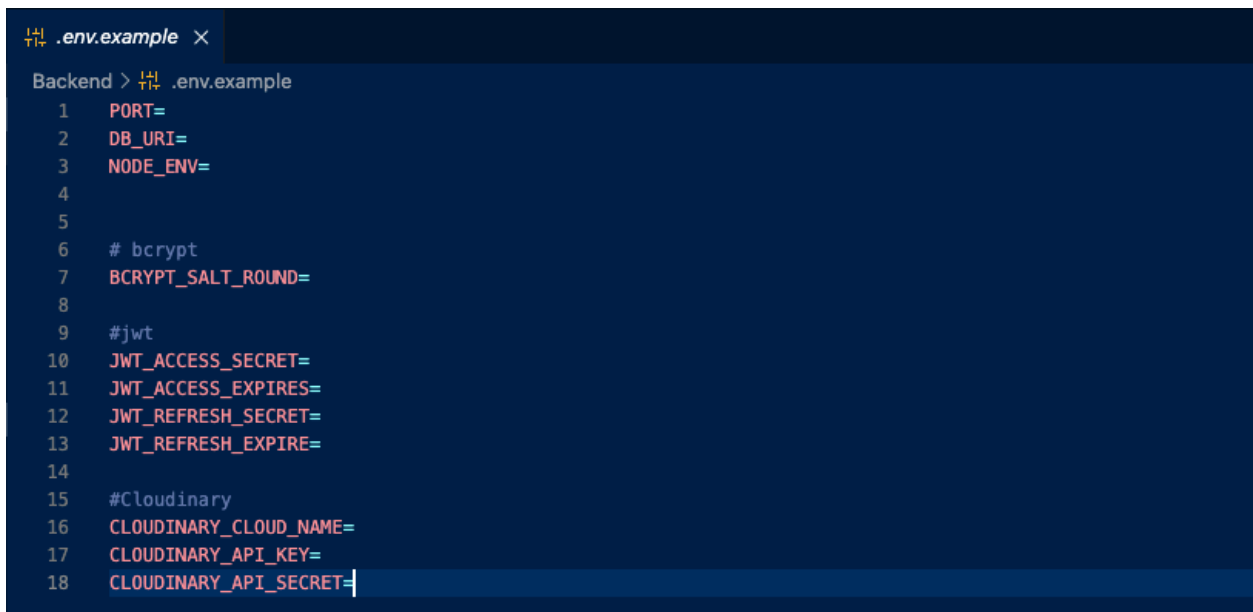

9. Environment Configuration

Environment variables are validated at startup to prevent missing keys.

Required `.env` fields:

- Database credentials
- JWT secrets & durations
- Cloudinary credentials
- Server port
- Bcrypt salt rounds

If any variable is missing, the server does not start.

A screenshot of a code editor with a dark theme. The editor has a tab at the top labeled ".env.example" with a close button. Below the tab, the text "Backend > .env.example" is visible. The main area contains a list of environment variables, each preceded by a line number from 1 to 18. The variables are: PORT=, DB_URI=, NODE_ENV=, # bcrypt, BCRYPT_SALT_ROUND=, #jwt, JWT_ACCESS_SECRET=, JWT_ACCESS_EXPIRES=, JWT_REFRESH_SECRET=, JWT_REFRESH_EXPIRE=, #Cloudinary, CLOUDINARY_CLOUD_NAME=, CLOUDINARY_API_KEY=, and CLOUDINARY_API_SECRET=. The cursor is positioned at the end of the last line.

```
1  PORT=
2  DB_URI=
3  NODE_ENV=
4
5
6  # bcrypt
7  BCRYPT_SALT_ROUND=
8
9  #jwt
10 JWT_ACCESS_SECRET=
11 JWT_ACCESS_EXPIRES=
12 JWT_REFRESH_SECRET=
13 JWT_REFRESH_EXPIRE=
14
15 #Cloudinary
16 CLOUDINARY_CLOUD_NAME=
17 CLOUDINARY_API_KEY=
18 CLOUDINARY_API_SECRET=
```

10. Development Workflow

Scripts

Command	Description
<code>npm run dev</code>	Development with auto-reload
<code>npm run build</code>	Compiles TypeScript to JavaScript
<code>npm start</code>	Starts production server

Deployment (Vercel)

- Build output: `dist/`
- Entry file: `dist/server.js`
- Vercel configuration handled via `vercel.json`
